Orchestrating Practical Multi-Agent Workflows

Demystifying the autonomous swarm through tightly framed LLM sessions, version control, and disciplined software engineering.

Myth vs. Reality Checklist

The Industry Hype

Self-directing swarm

Agents autonomously
talk to each other

Set and forget
decision making

The Engineering Blueprint

Human-routed architecture

PATH: /architecture/routing/human_controlled.yaml

Communicate strictly via
Git commits

PROTOCOL: git-commit-msg

Every significant decision
goes through a human

WORKFLOW: human_review_required=true

The intelligence is in the role definitions and the discipline of the workflow.
The LLMs simply provide the execution capacity.

STATEMENT: `human_input_priority > llm_execution`

What an Agent Actually Is

repo/

└─ .git/

└─ agents/

└─ the_conductor/

└─ the_architect/

└─ CLAUDE.md

Literally, an agent is a folder in a GitHub repo.

CLAUDE.md

Role: The Architect

Focus on structural integrity, scalability, and system design. Do not write implementation code.

When a session spins up, Claude Code points to this folder to read its specific frame of reference.

The Prompting vs. Agentic Framing Matrix

The Standard Prompt

"Act like a developer."

Unfocused. Spends compute figuring out orientation. Which developer? Front-end? Mainframe?

The Agentic Frame

Pre-built decision frameworks.

A. The Explorer

Prototypes fast, ignores edge cases.

B. The Villager

Writes production-grade code, full test coverage.

Centre of Gravity

Providing a specific frame mathematically shifts the LLM's micro-decisions, eliminating the need to guess the user's intent.

Concurrency vs. Capacity: The Sprint Squad Reality

Active concurrency: 3 to 5 agents.

Not all agents run simultaneously. Work is executed by very short-term squads running **focused, highly targeted sprints**.

The Core Assembly Line Journey

Step 1: The Input Quality Multiplier

The Failure Path

Vague Voice Memo

Direct feed

Vague Agent Output

The Blueprint Path

Voice Memo

Solid Brief

Exceptional, Actionable Output

Garbage in, garbage out. Agents do not receive raw materials or stream-of-consciousness ideas. The input to the workflow is strictly a clean, well-formatted brief.

Steps 2 & 3: The Librarian's Router

Git is the communication channel. Everything flows through commits.

The Librarian processes the initial brief and generates specific tasks for the required sub-agents.

Step 4: The Framing Funnel & Parallel Processing

Step 5: Review & Execute

No code is written without human **authorisation**. The human reviews the debriefing. Upon approval, Claude Code handles the parallel implementation across different parts of the codebase.

The Orchestration Layer: The Conductor

The Conductor is the **main agent**. It is just another **Claude session** with a specific **role definition**, used exclusively to **route work**, check statuses, request cross-agent updates, and **sync project state**.

The Hub-and-Spoke Architecture Synthesis

Agents never speak to one another directly. Git is the universal router and communication layer. This strictly enforces an inspectable audit trail via briefs, debriefs, and commits.

Engineering Principles & Tooling

Inflection Points

Execution Environment

Cloud over Local

Cloud sessions isolate execution environments (one **repo/branch** per session) for superior security and control.

The Tooling Inflection

Claude Code

The ability to instrument agents, define roles via markdown, and run sub-processes made this workflow possible.

The Productivity Reality

Hours, Not Days

Idea -> **Structured Brief** -> **Agent Review** -> **Implementation Started**.
Highly capable assistants coordinated through ultimate discipline compress the entire lifecycle.
